

# Advanced Topics in Cryptography

## Lecture 2

Benny Pinkas

Based on slides of Yehuda Lindell

# Zero Knowledge

---

- ▶ Prover  $P$ , verifier  $V$ , language  $L$
- ▶  $P$  proves that  $x \in L$  without revealing anything
  - ▶ **Completeness:**  $V$  always accepts when honest  $P$  and  $V$  interact
  - ▶ **Soundness:**  $V$  accepts with negligible probability when  $x \notin L$ , for any  $P^*$ 
    - ▶ Computational soundness: only holds when  $P^*$  is polynomial-time
- ▶ **Zero-knowledge:**
  - ▶ There exists a simulator  $S$  such that  $S(x)$  is indistinguishable from a real proof execution

# ZK Proof of Knowledge

---

- ▶ Prover  $P$ , verifier  $V$ , **relation  $R$**
- ▶  $P$  proves that it knows a witness  $w$  for which  $(x,w) \in R$  without revealing anything
  - ▶ The proof is zero knowledge as before
  - ▶ There exists an extractor  $K$  that can obtain from any  $P^*$ , a  $w$  such that  $(x,w) \in R$ , with the same probability that  $P^*$  convinces  $V$ .
- ▶ Equivalently:
  - ▶ The protocol securely computes the functionality
$$f_{zk}((x,w),x) = (-,R(x,w))$$

# Zero Knowledge

---

- ▶ An amazing concept; everything can be proven in zero knowledge
- ▶ Central to fundamental feasibility results of cryptography (e.g., GMW)
- ▶ But, can it be efficient?
  - ▶ It seemed that zero-knowledge protocols for “interesting languages” are complicated and expensive
- ▶ Zero knowledge is often avoided at significant cost

# Sigma Protocols

---

- ▶ A way to obtain efficient zero knowledge
  - ▶ Many general tools
  - ▶ Many interesting languages can be proven with a sigma protocol

# An Example – Schnorr DLOG

---

- ▶ Let  $G$  be a group of order  $q$ , with generator  $g$
- ▶  $P$  and  $V$  have input  $h \in G$ .  $P$  has  $w$  such that  $g^w = h$
- ▶  $P$  proves that to  $V$  that it knows  $\text{DLOG}_g(h)$ 
  - ▶  $P$  chooses a random  $r$  and sends  $a = g^r$  to  $V$
  - ▶  $V$  sends  $P$  a random  $e \in \{0, 1\}^t$
  - ▶  $P$  sends  $z = r + ew \pmod q$  to  $V$
  - ▶  $V$  checks that  $g^z = ah^e$
- ▶ Completeness
  - ▶  $g^z = g^{r+ew} = g^r(g^w)^e = ah^e$

# Schnorr's Protocol

## ▶ Proof of knowledge

- ▶ Assume **P** can answer two queries **e** and **e'** for the same **a**
- ▶ Then, it holds that  $\mathbf{g}^z = \mathbf{a}\mathbf{h}^e$ ,  $\mathbf{g}^{z'} = \mathbf{a}\mathbf{h}^{e'}$
- ▶ Thus,  $\mathbf{g}^z \mathbf{h}^{-e} = \mathbf{g}^{z'} \mathbf{h}^{-e'}$  and  $\mathbf{g}^{z-z'} = \mathbf{h}^{e-e'}$
- ▶ Therefore  $\mathbf{h} = \mathbf{g}^{(z-z')/(e-e')}$
- ▶ That is:  $\text{DLOG}_{\mathbf{g}}(\mathbf{h}) = (z-z')/(e-e')$

## ▶ Conclusion:

- ▶ If **P** can answer with probability greater than  $1/2^t$ , then it must know the dlog

# Schnorr's Protocol

---

- ▶ What about zero knowledge? This does not seem easy.
- ▶ But ZK holds if the verifier sends a random challenge  $e$
- ▶ This property is called “Honest-verifier zero knowledge”
  - ▶ The simulation:
    - ▶ Choose a random  $z$  and  $e$ , and compute  $a = g^z h^{-e}$
    - ▶ Clearly,  $(a, e, z)$  have the same distribution as in a real run, and  $g^z = ah^e$
- ▶ This is not a very strong guarantee, but we will see that it yields efficient general ZK.

# Definitions

---

- ▶ Sigma protocol template
  - ▶ **Common input:** **P** and **V** both have **x**
  - ▶ **Private input:** **P** has **w** such that  $(\mathbf{x}, \mathbf{w}) \in \mathbf{R}$
- ▶ **Protocol:**
  - ▶ **P** sends a message **a**
  - ▶ **V** sends a random **t**-bit string **e**
  - ▶ **P** sends a reply **z**
  - ▶ **V** accepts based solely on  $(\mathbf{x}, \mathbf{a}, \mathbf{e}, \mathbf{z})$

# Definitions

---

- ▶ **Completeness:** as usual
- ▶ **Special soundness:**
  - ▶ There exists an algorithm **A** that given any **x** and pair of transcripts  $(\mathbf{a}, \mathbf{e}, \mathbf{z}), (\mathbf{a}, \mathbf{e}', \mathbf{z}')$  with  $\mathbf{e} \neq \mathbf{e}'$  outputs **w** s.t.  $(\mathbf{x}, \mathbf{w}) \in \mathbf{R}$
- ▶ **Special honest-verifier ZK**
  - ▶ There exists an **M** that given any **x** and **e** outputs  $(\mathbf{a}, \mathbf{e}, \mathbf{z})$  which is distributed exactly like a real execution where **V** sends **e**

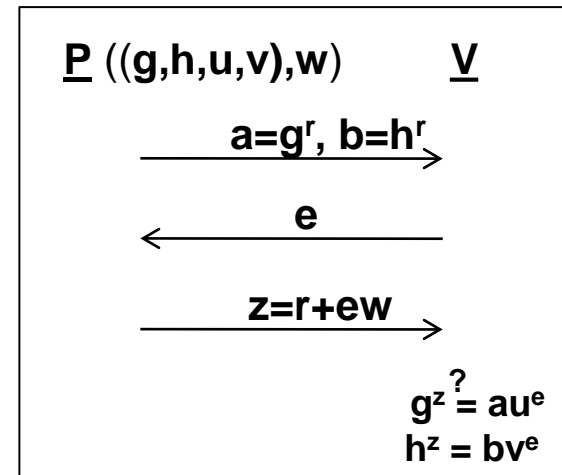

# Sigma Protocol for proving a DH Tuple

---

- ▶ Relation  $R$  of Diffie-Hellman tuples
  - ▶  $(g, h, u, v) \in R$  iff there exists  $w$  s.t.  $u = g^w$  and  $v = h^w$
  - ▶ Useful in many protocols
- ▶ This is a proof of membership, not of knowledge
- ▶ Protocol
  - ▶  $P$  chooses a random  $r$  and sends  $a = g^r$ ,  $b = h^r$
  - ▶  $V$  sends a random  $e$
  - ▶  $P$  sends  $z = r + ew \pmod q$
  - ▶  $V$  checks that  $g^z = au^e$ ,  $h^z = bv^e$

# Sigma Protocol DH Tuple

- ▶ Completeness: as in DLOG
- ▶ Special soundness:
  - ▶ Given  $(a,b,e,z), (a,b,e',z')$ , we have  $g^z = au^e, g^{z'} = au^{e'}, h^z = bv^e, h^{z'} = bv^{e'}$  and so like in DLOG on both
    - ▶  $w = (z - z') / (e - e')$
- ▶ Special HVZK
  - ▶ Given  $(g,h,u,v)$  and  $e$ , choose random  $z$  and compute
    - ▶  $a = g^z u^{-e}$
    - ▶  $b = h^z v^{-e}$

# Basic Properties

---

- ▶ Any sigma protocol is an interactive proof with soundness error  $2^{-t}$
- ▶ Properties of sigma protocols are invariant under parallel composition
- ▶ Any sigma protocol is a proof of knowledge with error  $2^{-t}$ 
  - ▶ The difference between the probability that  $\mathbf{P}^*$  convinces  $\mathbf{V}$  and the probability that an extractor  $\mathbf{K}$  obtains a witness is at most  $2^{-t}$
  - ▶ Proof needs some work

# Tools for Sigma Protocols

---

- ▶ Prove compound statements
  - ▶ AND, OR, subset
- ▶ ZK from sigma protocols
  - ▶ Can first make a compound sigma protocol and then compile it
- ▶ ZKPOK from sigma protocols

# AND of Sigma Protocols

---

- ▶ To prove the AND of multiple statements
  - ▶ Run all in parallel
  - ▶ Can use the same verifier challenge  $e$  in all
- ▶ Sometimes it is possible to do better than this
  - ▶ Statements can be batched
  - ▶ E.g. proving that many tuples are DDH can be done in much less time than running all proofs independently
    - ▶ Batch all into one tuple and prove

# OR of Sigma Protocols

---

- ▶ This is more complicated
  - ▶ Given two statements and two appropriate Sigma protocols, wish to prove that at least one is true, without revealing which
- ▶ The solution – an ingenious idea from [CDS]
  - ▶ Using the simulator, if  $e$  is known ahead of time it is possible to cheat
  - ▶ We construct a protocol where the prover can cheat in one out of the two proofs

# OR of Sigma Protocols

---

- ▶ The template for proving  $x_0$  or  $x_1$ :
  - ▶ **P** sends two first messages  $(a_0, a_1)$
  - ▶ **V** sends a single challenge  $e$
  - ▶ **P** replies with
    - ▶ Two challenges  $e_0, e_1$  s.t.  $e_0 \oplus e_1 = e$
    - ▶ Two final messages  $z_0, z_1$
  - ▶ **V** accepts if  $e_0 \oplus e_1 = e$  and  $(a_0, e_0, z_0), (a_1, e_1, z_1)$  are both accepting
- ▶ How does this work?

# OR of Sigma Protocols

---

- ▶ **P** sends two first messages  $(\mathbf{a}_0, \mathbf{a}_1)$ 
  - ▶ Suppose that **P** has a witness for  $\mathbf{x}_0$  (but not for  $\mathbf{x}_1$ )
  - ▶ **P** chooses a random  $\mathbf{e}_1$  and runs SIM to get  $(\mathbf{a}_1, \mathbf{e}_1, \mathbf{z}_1)$
  - ▶ **P** sends  $(\mathbf{a}_0, \mathbf{a}_1)$
- ▶ **V** sends a single challenge  $\mathbf{e}$
- ▶ **P** replies with  $\mathbf{e}_0, \mathbf{e}_1$  s.t.  $\mathbf{e}_0 \oplus \mathbf{e}_1 = \mathbf{e}$  and with  $\mathbf{z}_0, \mathbf{z}_1$ 
  - ▶ **P** already has  $\mathbf{z}_1$  and can compute  $\mathbf{z}_0$  using the witness
- ▶ Soundness
  - ▶ If **P** doesn't know a witness for  $\mathbf{x}_1$ , he can only answer for a single  $\mathbf{e}_1$
  - ▶ This means that  $\mathbf{e}$  defines a single challenge  $\mathbf{e}_0$ , like in a regular proof

# OR of Sigma Protocols

---

- ▶ Special soundness

- ▶ Relative to first message  $(a_0, a_1)$ , and two different  $e, e'$ , it holds that either  $e_0 \neq e'_0$  or  $e_1 \neq e'_1$  (because  $e_0 \oplus e_1 = e$  and  $e'_0 \oplus e'_1 = e'$ ).
- ▶ Thus, we will obtain two different continuations for **at least** one of the statements, and from the special soundness of a single protocol it is possible to compute a witness for that statement, which is also a witness for the OR statement.

- ▶ Honest verifier ZK

- ▶ Can choose both  $e_0, e_1$ , so no problem
- ▶ Note: it is possible to prove an OR of different statements using different protocols

# OR of Many Statements

---

- ▶ Prove **k out of n** statements  $x_1, \dots, x_n$ 
  - ▶ **A** = set of indices that prover knows how to prove; the other indices are denoted as **B**
  - ▶ Use secret sharing with threshold **n-k**
  - ▶ Field elements  $1, 2, \dots, n$ , polynomial **f** with free coefficient **s**
  - ▶ Share of **s** for party **P<sub>i</sub>**: **f(i)**
- ▶ Prover
  - ▶ For every  $i \in \mathbf{B}$ , prover generates  $(\mathbf{a}_i, \mathbf{e}_i, \mathbf{z}_i)$  using SIM
  - ▶ For every  $j \in \mathbf{A}$ , prover generates  $\mathbf{a}_j$  as in protocol
  - ▶ Prover sends  $(\mathbf{a}_1, \dots, \mathbf{a}_n)$

# OR of Many Statements

---

- ▶ Prover sent  $(\mathbf{a}_1, \dots, \mathbf{a}_n)$
- ▶ Verifier sends a random field element  $e \in F$
- ▶ Prover finds the polynomial  $f$  of degree  $n-k$  passing through all  $(i, e_i)$  and  $(0, e)$  (for  $i \in B$ )
  - ▶ The prover computes  $e_j = f(j)$  for every  $j \in A$
  - ▶ The prover computes  $\mathbf{z}_j$  as in the protocol, based on transcript  $\mathbf{a}_j, e_j$
- ▶ Soundness follows because there are  $|F|$  possible vectors and the prover can only answer one

# General Compound Statements

---

- ▶ This can be generalized to any monotone formula (meaning that the formula contains AND/OR but no negations)
- ▶ See Cramer, Damgård, Schoenmakers, Proofs of partial knowledge and simplified design of witness hiding protocols, CRYPTO'94.
