## Constructions of Oblivious Transfer

## Security Definitions for OT

- Defining what is means to protect the receiver's privacy is easy, since the sender receives no output in the ideal model and should therefore learn nothing about the receiver's input.
- Receiver's privacy indistinguishability
  - For any values of the sender's inputs x<sub>0</sub>,x<sub>1</sub>, the sender cannot distinguish between the case that the receiver's input is 0 and the case that it is 1.

## Security Definitions for OT

- Definition of sender's security:
  - For every algorithm A' that the receiver might run in the real implementation of oblivious transfer
  - there is an algorithm A" that the receiver can run in the ideal implementation
  - such that for any values of  $x_0, x_1$  the outputs of A' and A'' are indistinguishable.
  - Namely, the receiver in the real implementation does not learn anything more than the receiver in the ideal implementation.
- This definition does not handle delicate issues, such as whether the receiver "knows" j or the sender "knows"  $x_0, x_1$

The Even-Goldreich-Lempel 1-out-of-2 OT construction (providing security only against semi-honest adversaries)

- Setting:
  - Sender has two inputs,  $x_0$ ,  $x_1$ .
  - Receiver has an input  $j \in \{0, 1\}$ .
- Protocol:
  - Receiver chooses a random public/private key pair (*E*,*D*).
  - It sets PK<sub>j</sub>=E, and chooses PK<sub>1-j</sub> at random from the same distribution as that of public keys<sup>\*</sup>. It then sends (PK<sub>0</sub>, PK<sub>1</sub>) to the sender.
  - The sender encrypts  $x_0$  with  $PK_0$ , and  $x_1$  with  $PK_1$ , and sends the results to the receiver.
  - The receiver decrypts  $x_{i}$ .
  - Why is this secure against semi-honest adversaries?
- (\*) It is required that it is possible to sample items with the exact distribution of public keys, and do this without knowing how to decrypt the resulting ciphertexts.

#### The Bellare-Micali Construction (providing security against malicious adversaries)

#### Preliminaries:

- $G_q$  is a subgroup of order q of  $Z_p^*$ , where p is prime and p=2q+1.
- The OT protocol is secure assuming that the Computational Diffie-Hellman assumption holds for  $G_q$ .
- The Computational Diffie-Hellman assumption (CDH) is that the following problem is hard:
  - The input to the problem is a generator g and values g<sup>a</sup>, g<sup>b</sup> generated with random a, b ∈ [1,q].
  - The task is to find  $z=g^{a\cdot b}$ .
- (There is no need to use here the Decisional Diffie-Hellman problem)

## The Bellare-Micali Construction

- Initialization: The sender chooses a random C in  $G_q$ .
- Protocol: (slightly modified)
  - The receiver picks a random  $k \in [1,q]$ , sets public keys  $PK_j = g^k$ , and  $PK_{1-j} = C/PK_j$ . It sends  $PK_0$  to the sender.
  - The sender computes  $PK_1 = C/PK_0$ . Chooses a random *r*.
  - Generates El Gamal encryptions:
    - $E_0 = (g^r, H((PK_0)^r) \oplus x_0), E_1 = (g^r, H((PK_1)^r) \oplus x_1), \text{ and sends them to the receiver.}$
  - The receiver computes  $H((PK_j)^r)$  and decrypts  $E_j$ .
- Security:
  - Sender cannot learn anything about *j* (unconditionally).
  - The receiver cannot compute the discrete logs of both  $PK_0$ and  $PK_1$ . (why?) (why does this imply security?  $\Rightarrow$ )

## Security of the Bellare-Micali Construction

- The receiver cannot compute the discrete logs of both  $PK_0$  and  $PK_1$ .
- The Computational Diffie-Hellman assumption implies that it cannot compute both (PK<sub>0</sub>)<sup>r</sup> and (PK<sub>1</sub>)<sup>r</sup>:
  - Computing both  $(PK_0)^r$  and  $(PK_1)^r$ , implies that the receiver can also compute  $C^r$ .
  - CDH:  $(g, g^a, g^b) \rightarrow g^{ab}$  is hard
  - The receiver only knows g,C,g<sup>r</sup> (for random C and r), and CDH implies that it cannot compute C<sup>r</sup>.
- There is therefore an index *i* such that the receiver does not know (*PK<sub>i</sub>*)<sup>r</sup>
  - If we assume that H() is a random function (a random oracle) then the receiver cannot distinguish H((PK<sub>i</sub>)<sup>r</sup>) from a random string.

### Security of the Bellare-Micali Construction

- To complete the proof, based on the observations given in the previous slide, we must show a proof of security by simulation, namely show that:
  - For every algorithm A' that the receiver might run in the real implementation of oblivious transfer
  - there is an algorithm A" that the receiver can run in the ideal implementation
  - such that for any values of  $x_0, x_1$  the outputs of A' and A'' are indistinguishable.

# OT secure against malicious adversaries, without random oracles [NP]

#### Security is based on the DDH assumption alone.

- Security is proven according to the definition given before, ensuring only privacy, rather than proving full security.
- The Decisional Diffie-Hellman assumption (DDH)
  - > The following problem is hard:
  - The input to the problem is
    - ▶ a generator *g*
    - ▶ values  $g^a$ ,  $g^b$  generated with random  $a, b \in [1, q]$
    - and a value g<sup>c</sup> where with probability ½, c was chosen at random in [1,q], and with probability ½, c=ab.
  - The task is to decide whether c = ab, or is random.

# OT secure against malicious adversaries, without random oracles [NP]

- Security is based on the DDH assumption alone.
- $Z_p^*$ , q, and sender's and receiver's inputs are as before.
- Receiver
  - chooses random  $a, b, c_{1-j} \in [1,q]$ , and defines  $c_j = ab \pmod{q}$ .
  - It sends to the sender  $(g^a, g^b, g^{c0}, g^{c1})$ .

#### The sender

- Certifies that  $g^{c0} \neq g^{c1}$ . Chooses random  $s_0, r_0, s_1, r_1 \in [1, q]$ .
- Defines  $w_0 = (g^a)^{s_0} g^{r_0}$ . Encrypts  $x_0$  with the key  $(g^{c_0})^{s_0} (g^b)^{r_0}$ .
- Defines  $w_1 = (g^a)^{s_1} g^{r_1}$ . Encrypts  $x_1$  with the key  $(g^{c_1})^{s_1} (g^b)^{r_1}$ .
- Sends  $w_0$ ,  $w_1$  and the encryptions to receiver.
- Receiver computes (w<sub>j</sub>)<sup>b</sup> which is the key with which x<sub>j</sub> was encrypted. It uses it to and decrypt x<sub>j</sub>.

## **Properties**

#### Correctness

- Suppose j=0. R sends (g<sup>a</sup>, g<sup>b</sup>, g<sup>ab</sup>, g<sup>c</sup>).
- S defines w₀=(g<sup>a</sup>)<sup>u0</sup>g<sup>v0</sup>.
- S encrypts  $x_0$  with  $k_0 = (g^{ab})^{u0} (g^b)^{v0}$ .
  - Note that encryption key is equal to  $(w_0)^b$ .
- R computes  $k_0 = (w_0)^b$  and uses it for decryption.

#### Overhead:

- R computes 5 exponentiations.
- S computes 8 exponentiations.

## Privacy – malicious sender

- Receiver's security
  - Based on the DDH assumption
  - Must show that sender's view is indistinguishable regardless of receiver's input.
    - Sender receives either (g<sup>a</sup>, g<sup>b</sup>, g<sup>ab</sup>, g<sup>c</sup>) or (g<sup>a</sup>, g<sup>b</sup>, g<sup>c</sup>, g<sup>ab</sup>).
    - Suppose that it can distinguish between the two cases.
    - We can construct a distinguisher for the DDH problem, which distinguishes between (g<sup>a</sup>,g<sup>b</sup>,g<sup>ab</sup>) and (g<sup>a</sup>,g<sup>b</sup>,g<sup>c</sup>):
    - The distinguisher receives (g<sup>a</sup>,g<sup>b</sup>,X) and (g<sup>a</sup>,g<sup>b</sup>,Y), and sends (g<sup>a</sup>,g<sup>b</sup>,X,Y) to S.

## Privacy – malicious receiver

- The security of the server is unconditional.
  - Does not depend on any cryptographic assumption.
- Suppose that j=0.
- Regarding x<sub>1</sub>, the server sends
  - ► w<sub>1</sub>=(g<sup>a</sup>)<sup>u1</sup>g<sup>v1</sup>.
  - $x_1$  is then encrypted with the key  $k_1 = (g^c)^{u1} (g^b)^{v1}$ .
  - The values  $u_1, v_1$  were chosen at random, and  $ab \neq c_1$ .
  - ▶ **Claim:** (w<sub>1</sub>,k<sub>1</sub>) are uniformly distributed.
  - Therefore the message (w<sub>1</sub>,k<sub>1</sub>) sent by S about x<sub>1</sub> can be easily simulated.

## Privacy – malicious receiver

#### Proof of claim:

- $W_1 = (g^a)^{u_1} g^{v_1} = g^{a \cdot u_1 + v_1}$ .
- $k_1 = (g^c)^{u1} (g^b)^{v1} = g^{c \cdot u1 + b \cdot v1} = (g^{(c/b) \cdot u1 + v1})^b$ .
- Define  $F(x) = u_1 x + v_1$ . F(x) is pair-wise independent:
  - ►  $\forall x,y,s,t \text{ Prob}(F(x)=s \& F(y)=t) = 1/|G|^2$
- ▶ w<sub>1</sub>=g<sup>F(a)</sup>.
- ►  $k_1 = (g^{F(c/b)})^b$ .
- $c \neq ab$  and therefore F(a) and F(c/b) are uniformly distributed.
- ►  $\Rightarrow$  (w<sub>1</sub>,k<sub>1</sub>) are uniformly distributed.
