1-out-of-N OT

- A generalization of 1-out-of-2 OT:
- Sender has N inputs, $x_0,...x_N$.
- Receiver has an input $j \in \{1,2,...,N\}$.
- Output:
- Receiver learns x_i and nothing else.
- Sender learns nothing about j.
- We would like to construct 1-out-of-N OT, or reductions from 1-out-of-N OT to 1-out-of-2 OT.
- It was shown that any such reduction which provides unconditional security requires at least N-1 OTs.
- Since OT has a high computational overhead, we would like to do better than that.

Construction 1: A recursive protocol for 1-out-of-N OT

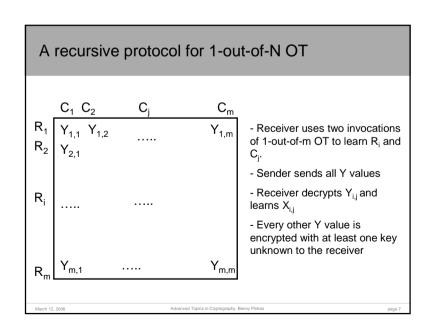

- The reduction uses a pseudo-random function $F_k()$.
 - It holds that if k is chosen at random and kept secret, no adversary can distinguish between (x,F_k(x)) and a random value, for every x.
- The protocol reduces 1-out-of-m OT to 1-out-of-√m OT.
 This can done recursively.

A recursive protocol for 1-out-of-N OT Sender's original input: $X_{1,1} X_{1,2}$ X_{m,1} $X_{m,m}$ Advanced Topics in Cryptography, Benny Pinkas

Construction 2: a reduction to 1-out-of-2 OT

- Assume N=2ⁿ. The receiver's input is $j=j_n,...,j_1$.
- Preprocessing: the sender prepares 2n keys
- $-(k_{1,0},k_{1,1}),(k_{2,0},k_{2,1}),...,(k_{n,0},k_{n,1}).$
- and encryptions $Y_i = X_i \oplus F_{K_{-1,i1}}(i) \oplus \ldots \oplus F_{K_{-1,in}}(i)$ (namely, X_i is encrypted using the keys corresponding to the bits of i).
- For each $1 \le s \le n$, the parties run a 1-out-of-2 OT:
- The sender's input is $(k_{s,0}, k_{s,1})$.
- The receiver's input is j_s .
- The sender sends $Y_1, ..., Y_n$ to the receiver.
- The receiver reconstructs x_i.
- Why can't we use $Y_i = X_i \oplus K_{1,i1}(i) \oplus ... \oplus K_{1,in}(i)$?

Advanced Topics in Cryptography, Benny Pinkas

Analysis

- Overhead:
- N=logN invocations of 1-out-of-2 OT (this is the bulk of the overhead).
- The preprocessing stage requires NlogN invocations of the pseudo-random function *F*(*)*.
- Receiver privacy (hand-waving):
- Since the 1-out-of-2 OTs do not leak information about the receiver's input.
- Sender privacy:
- It can be shown that if the receiver learns about more than a single item, then either the 1-out-of-2 OT is not secure, or F() is not pseudo-random.

Secure two-party computation - definition

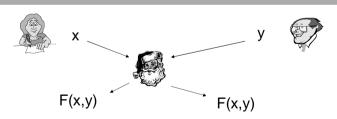

March 12, 20

Advanced Topics in Cryptography, Benny Pinkas

Does the trusted party scenario make sense?

- We cannot hope for more privacy
- Does the trusted party scenario make sense?
 - Are the parties motivated to submit their true inputs?
 - ullet Can they tolerate the disclosure of F(x,y)?
- If so, we can implement the scenario without a trusted party.

Fairness, aka early termination

- Suppose both parties (A and B) need to learn the output
- Assume that the last message in the protocol goes from A to B
- A malicious A does not send that message
- \Rightarrow B does not learn output
- There is no perfect solution to this problem. However, this corrupt behavior is detectable.

March 12, 2006

Advanced Topics in Cryptography, Benny Pinkas

---- 40

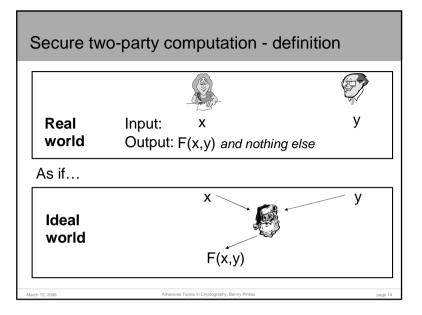

Definition

- For every A in the real world, there is an A' in the ideal world, s.t. whatever A can compute in the real world. A' can compute in the ideal world
- The same for B. Need not worry about the case the both are corrupt.
- <u>Semi-honest case:</u> (A' behaves according to the protocol.)
- It is sufficient to require that A' is able to simulate the interaction from the output alone.

page 15

Examples of Simple Privacy Preserving Primitives

- Reasonably efficient solutions satisfying the definition above.
 - Is X > Y? Is X = Y?
 - What is $X \cap Y$? What is median of $X \cup Y$?
 - Auctions (negotiations). Many parties, private bids. Compute the winning bidder and the sale price, but nothing else.
 - Add privacy to existing data mining algs.

__

Secure two-party computation of general functions [Yao]

- First, represent the function F as a Boolean circuit C
- It's always possible
- Sometimes it's easy (additions, comparisons)
- Sometimes the result is inefficient (e.g. for indirect addressing)

Garbling the circuit

• Bob (aka "the constructor") constructs the circuit, and then garbles it.

 $W_k^0 \equiv 0$ on wire k $W_k^1 \equiv 1$ on wire k

(Alice will learn one string per wire, but not which bit it corresponds to.)

March 12, 200

Advanced Topics in Cryptography, Benny Pinkas

page 19

Basic ideas

- · A simple circuit is evaluated by
 - setting values to its input gates
- For each gate, computing the value of the outgoing wire as a function of the wires going into the gate.
- Secure computation:
- No party should learn the values of any wires, except for the output wires of the circuit
- · Yao's protocol
- A compiler which takes a circuit and transforms it to a circuit which hides all information but the final output.

March 12, 20

Advanced Topics in Cryptography, Benny Pinkas

Gate tables

- For every gate, every combination of input values is used as a key for encrypting the corresponding output
- Assume G=AND. Bob constructs a table:
- Encryption of w_k^0 using keys w_i^0, w_J^0
- Encryption of w_k⁰ using keys w_i⁰,w_J¹
- Encryption of w_k⁰ using keys w_i¹,w_J⁰
- Encryption of w_k¹ using keys w_i¹,w_J¹
- ...and permutes the order of the entries
- Result: given w_ix,w_iy, can compute w_kG(x,y)
- (encryption can be done using a prf)

ige 20

The encryption scheme being used

- The encryption scheme must be secure even if many messages are encrypted with the same key
- Therefore, a one-time pad is not a good choice.
- Motivation: a wire might be used in many gates, and the corresponding garbled value is used as an encryption key in each of them.
- It must hold that a random string happens to be a correct ciphertext only with negligible probability.
- So that when Alice tries to decrypt the entries in the table, she will only be successful for on entry.

March 12 2006

Advanced Topics in Cryptography, Benny Pinkas

---- 04

Secure computation

- · Bob sends to Alice
- Tables encoding each circuit gate.
- Garbled values (w's) of his input values.
- If Alice gets garbled values (w's) of her input values, she can compute the output of the circuit, and nothing else.
- Why can't the Bon provide Alice with the keys corresponding to both 0 and 1 for her input wires?

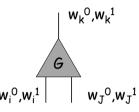

March 12, 20

Advanced Topics in Cryptography, Benny Pinkas

page 23

Secure computation

- · Bob sends the table of gate G to Alice
- Given, e.g., w_i⁰, w_j¹, Alice computes w_k⁰, but doesn't know the
 actual values of the wires.
- Alice cannot decrypt the entries of input pairs different from (0,1)
- For the wires of circuit output:
- Bob does not define "garbled" values for the output wires, but rather encrypts a 0/1 value.

March 12, 2006

Advanced Topics in Cryptography, Benny Pinkas

---- 00

Alice's input

- For every wire i of Alice's input:
- The parties run an OT protocol
- Alice's input is her input bit (s).
- Bob's input is w_i⁰,w_i¹
- Alice learns wis
- The OTs for all input wires can be run in parallel.
- Afterwards Alice can compute the circuit by herself.

aye z=

Secure computation – the big picture (simplified)

- Represent the function as a circuit C
- Bob sends to Alice 4|C| encryptions (e.g., 50|C| Bytes).
- Alice performs an OT for every input bit. (Can do, e.g. 100 OTs per sec.)
- Relatively low overhead:
- Constant number of (~1) rounds of communication.
- Public key overhead depends on the size of Alice's input
- Communication depends on the size of the circuit
- Efficient for medium size circuits!

March 12 2006

Advanced Topics in Cryptography, Benny Pinkas

---- 05

Example

- Comparing two N bit numbers
- What's the overhead?

March 12, 20

Advanced Topics in Cryptography, Benny Pinkas

Secure computation: security (semi-honest case)

- In the protocol:
- Bob sends tables to Alice
- The parties run OTs where Alice learns garbled values
- Alice computes the output of the circuit
- A corrupt Bob: sees the execution of the OTs. If OTs are secure learns nothing about Alice's input.
- A corrupt Alice:
- Since OTs are secure, learns one garbled value per inptu wire.
- In every gate, if she knows only one garbled value of every input wire, she cannot decrypt more than a single value of output wire.
- A simulation argument appears at "A Proof of Yao's Protocol for Secure Two-Party Computation"

nane 26

Applications

- Two parties. Two large data sets.
- Max?
- Mean?
- Median?
- Intersection?

March 12, 200

Advanced Topics in Cryptography, Benny Pinkas

page 28

Conclusions

- If the circuit is not too large:
- Efficient secure two-party computation.
- Efficient multi-party computation with two semi-trusted parties.
- An "open" question: >2 semi-trusted parties.
- If the circuit is large: we currently need ad-hoc solutions.
